

WASTE-TO-ENERGY

**Vienna Marriott Hotel, Vienna, Austria
18-19 September 2017**

Impact of the increased fraction of industrial waste on the emissions from waste-to-energy plants

Federico Viganò

**Department of Energy - Politecnico di Milano
*LEAP Lab & MatER Study Center***

Research Center established at the end of 2010

MISSION: Establishing scientific bases for the many issues related to recovery from waste

Main goal: Give a rigorous scientific definition of the technologies and the policies which can be adopted for material and energy recovery, contributing to identify the most effective options for sustainable, economically viable waste management practices.

Support of public and industrial partners

MatER has established strong relationships with International research centers & Networks:

The diagram depicts a classical temple structure. At the top is a triangular pediment containing the word 'Sustainability' in green. Two columns support the pediment. Between the columns are two boxes: a green one labeled 'Materials recovery' and an orange one labeled 'Energy recovery', connected by a double-headed blue arrow. A red oval encircles these two boxes. Below the columns are two rectangular steps: the top one is labeled 'Reuse' and the bottom one is labeled 'Reduction'.

Sustainability

Materials
recovery

Energy
recovery

Reuse

Reduction

**Materials and Energy
recovery are BOTH
ESSENTIAL for
Sustainability**

Strict interconnection between
the two forms of recovery:

- Materials recovery generates residues that can be sent to energy recovery
- Energy recovery generates residues that can be sent to materials recovery

Increased fraction of industrial waste to WtE plants

Plant A

Plant B

Plant C

Plant D

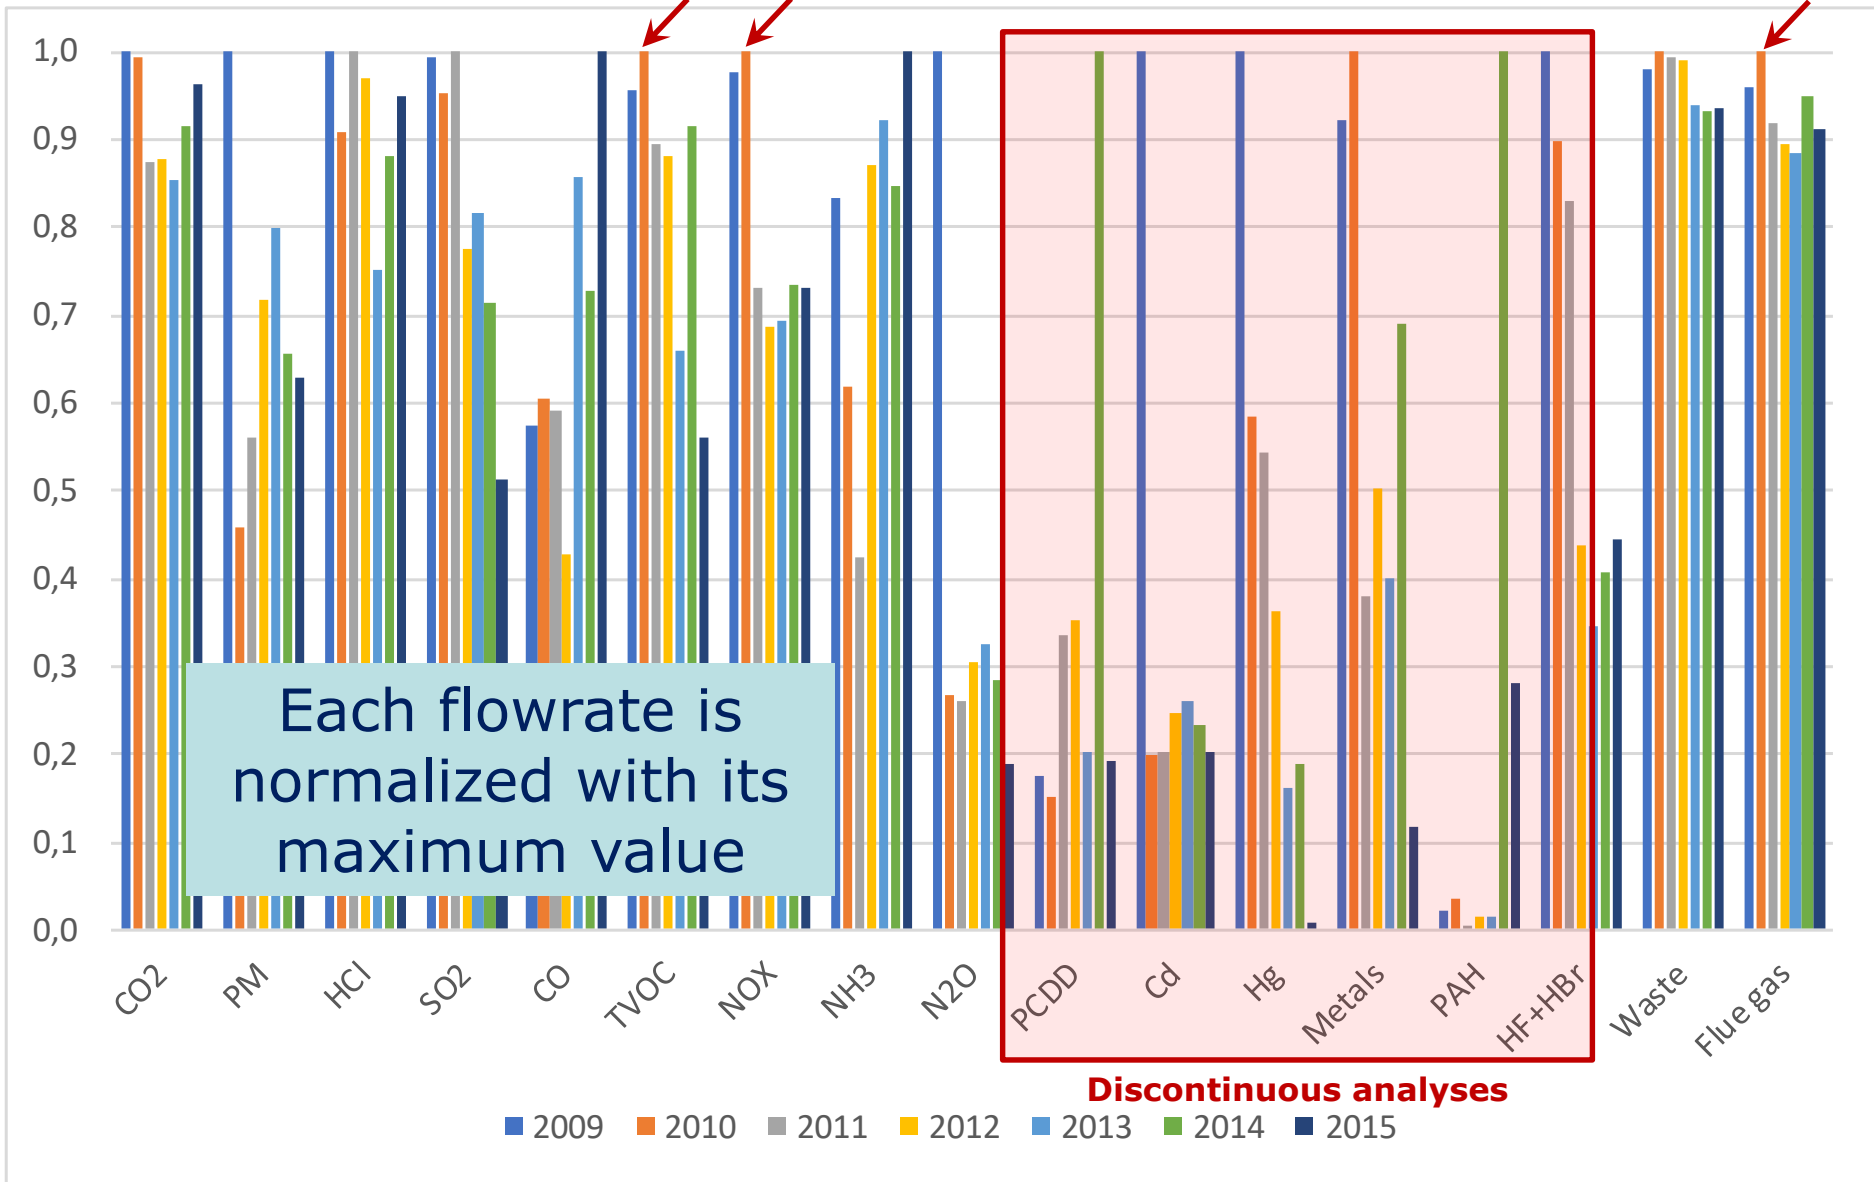

DO EMISSIONS INCREASE?

**In addition to peculiar pollutants, possibly brought by specific waste streams
IS THERE ANY EFFECT ON THE EMISSIONS OF GENERAL POLLUTANTS?**

$$\text{EMISSION [kg/s]} = \text{FLOWRATE OF FLUE GAS [Nm}^3\text{/s]} \times \text{CONCENTRATION [kg/Nm}^3\text{]}$$

The CONCENTRATION on Dry, Normalized, Referred to 11% O₂ (DNR) basis of a pollutant, which is controlled by APC system (eg. NO_x, HCl), can be assumed CONSTANT as far as the plant is operated within its design limits

HOW does the flowrate of flue gas (DNR) depend on the nature of the treated waste?

For the purpose of mass and energy balance of combustion, this simple scheme is adequate.

Ash: inert materials that do not participate actively to combustion

Moisture: liquid water that absorbs its latent heat of evaporation (= LHV = -2.44 MJ/kg) during combustion

Combustible matter: peculiar of each different substance contained in the waste

Survey of data on combustible matter (DAF = Dry Ash Free basis)
of materials that can be reasonably sent to WtE plants

10 literature sources (collections of data)

460 records

of which **~400** on possible waste materials
classified according to **14** categories (eg. paper, plastics)

Properties considered:

H/C, O/C, N/C, ... ratios

C, H, O, N, ... mass contents

LHV

DAD: Day Air Demand for stoichiometric combustion
($\text{Nm}^3/\text{kg}_{\text{DAF}}$ and $\text{Nm}^3/\text{MJ}_{\text{DAF}}$)

DSFG: Dry Stoichiometric Flue Gas production
($\text{Nm}^3/\text{kg}_{\text{DAF}}$ and $\text{Nm}^3/\text{MJ}_{\text{DAF}}$)

Mass balance can be well simulated by considering only C, H and O contents, with the balance being N

→ Mean error on the prediction of DAD and DSFG ($\text{Nm}^3/\text{kg}_{\text{DAF}}$) ≈ 0

→ Corresponding std. deviation $\pm 1.2\%$ (due to the error in the evaluation of the molar mass)

$$\rightarrow \text{dad}_{\text{DAF}} = f(y_{\text{C}}, y_{\text{H}}, y_{\text{O}}); \text{dsfg}_{\text{DAF}} = g(y_{\text{C}}, y_{\text{H}}, y_{\text{O}})$$

LHV_{DAF} calculated by linear correlation of C, H, O, N contents

→ Boie's correlation is the best among 10 linear correlations

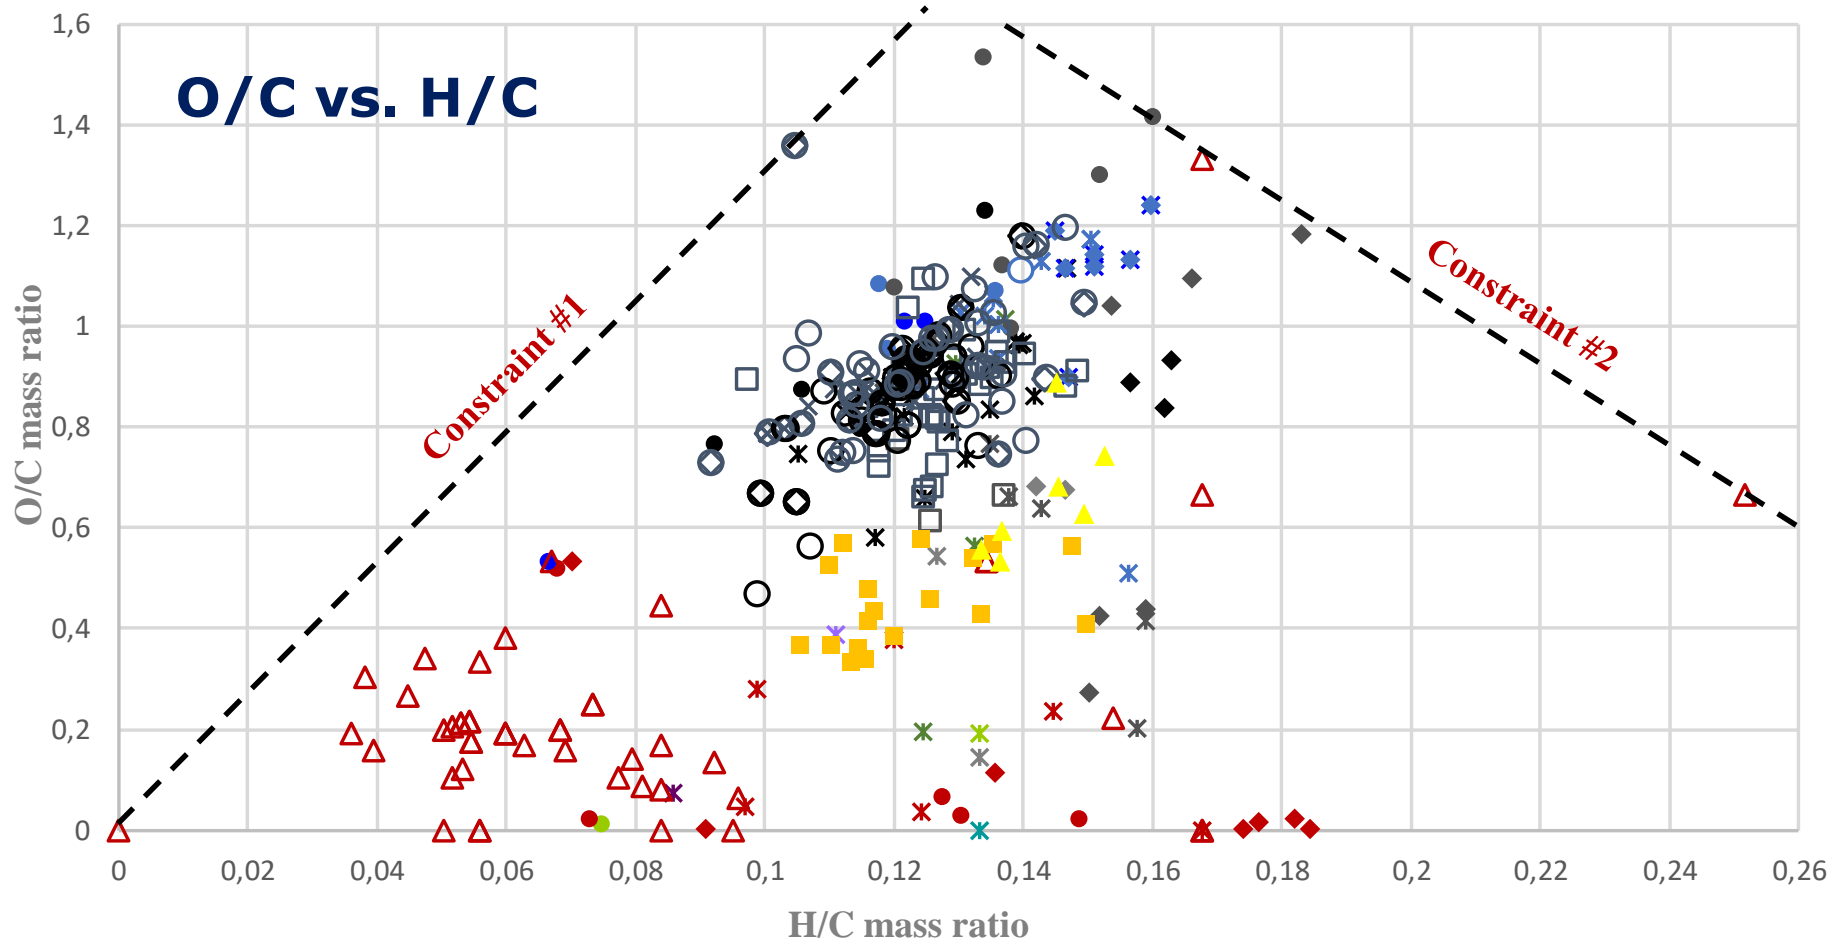

$$\rightarrow \text{LHV}_{\text{DAF}} = 0.3517 * y_{\text{C}}\% + 0.944 * y_{\text{H}}\% - 0.111 * y_{\text{O}}\% (+0.1047 * y_{\text{S}}\%)$$

→ Mean error on the prediction of LHV ≈ 0

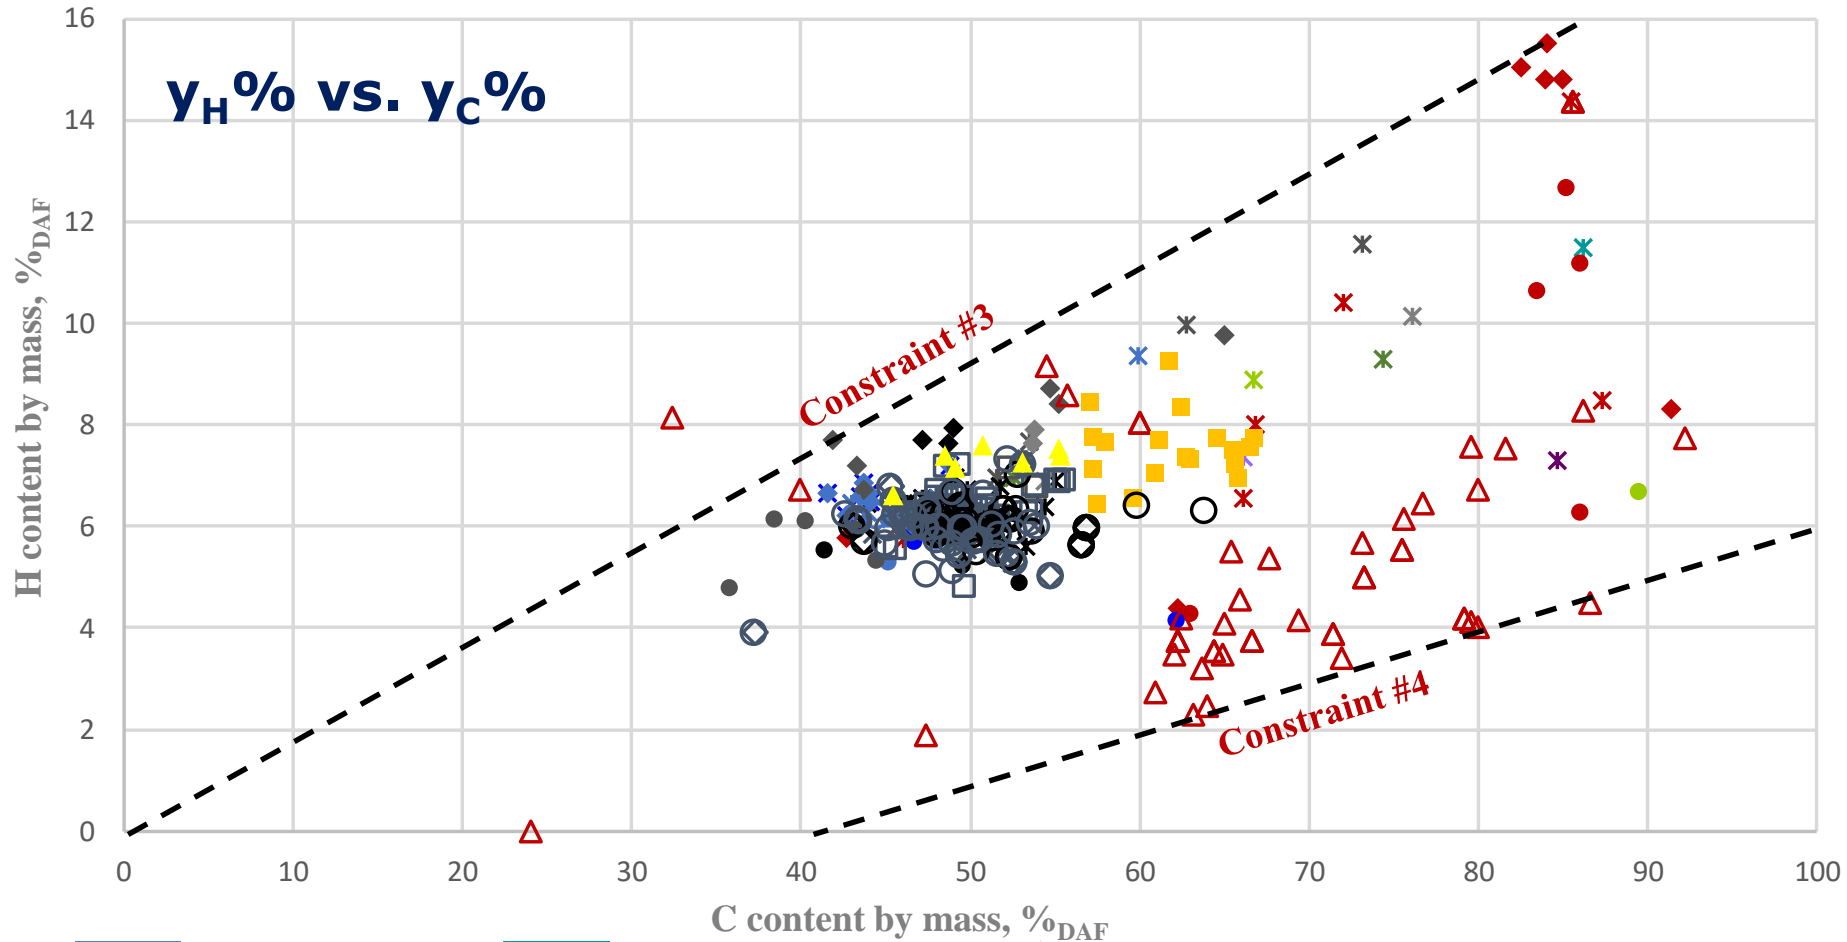

→ Corresponding std. deviation (σ) $\pm 9.0\%$

$$\rightarrow \text{LHV}_{\text{DAF}} = h(y_{\text{C}}, y_{\text{H}}, y_{\text{O}}) * (1+x) \text{ with } x \text{ in } [-2\sigma, +2\sigma] \text{ for } 95\% \text{ of cases}$$

Some ranges of variation are identified for properties

14 categories of materials (colors); 10 literature sources (marker shapes).

	Paper and cardboard		Rubber
	Food and Food Wastes		Plastics
	Trees, Wood, Brush, Plants		Other biogenic materials (eg. Linoleum)
	Mixed textiles/paper		Textiles
	Tires		Sanitary waste
	Animal matter (eg. Leather)		Agricultural residues
	Domestic waste		Sewage sludge

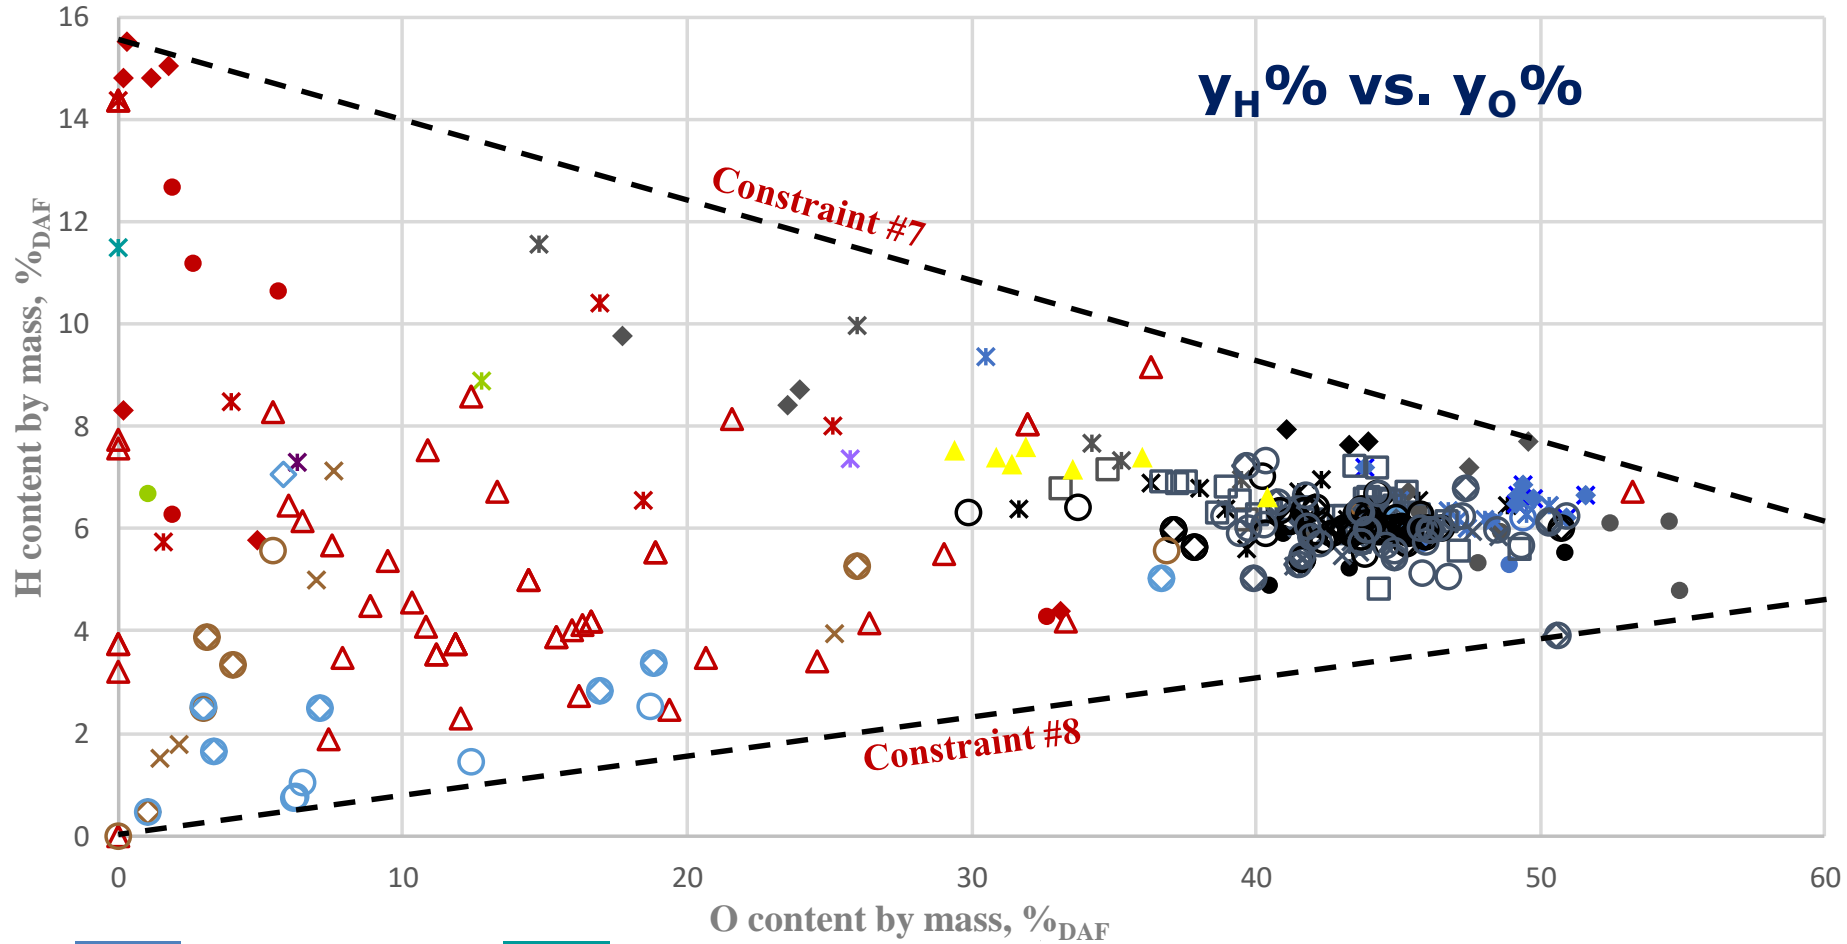

14 categories of materials
(colors); 10 literature
sources (marker shapes).

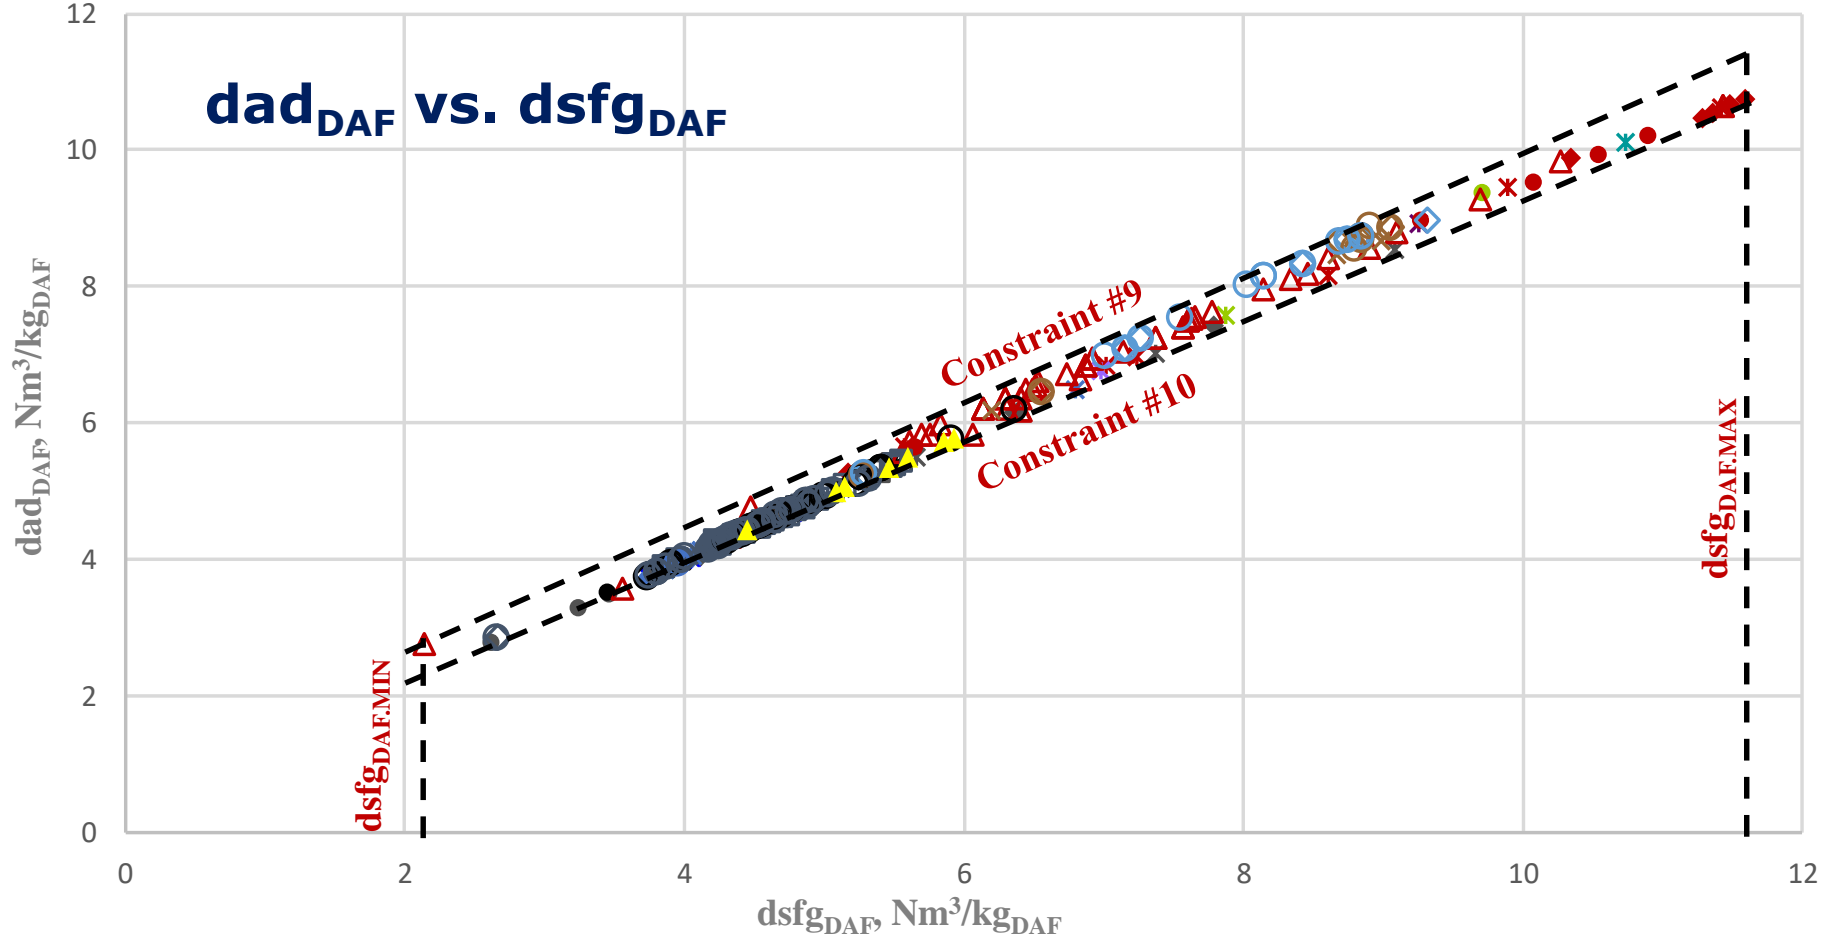

- Paper and cardboard

Any waste can be modelled as a mix of six components:
C, H, O, N, Ash, Moisture

- **The properties characterizing such a mix are subjected to some constraints (12 have been found)**
- **LHV can be predicted based on such properties with $\pm 18\%$ accuracy at $\sim 95\%$ confidence level**

When the waste is fed to a WtE plant, its properties must also respect technological and operating limitations (i.e. other constraints)

Technological limitations

MIN & MAX moisture content

MIN & MAX ash content

MIN & MAX LHV

Technological and operating limitations

Let's focus on MCR combustion power $\rightarrow LHV \cdot M_W = P_{COMB, MCR}$

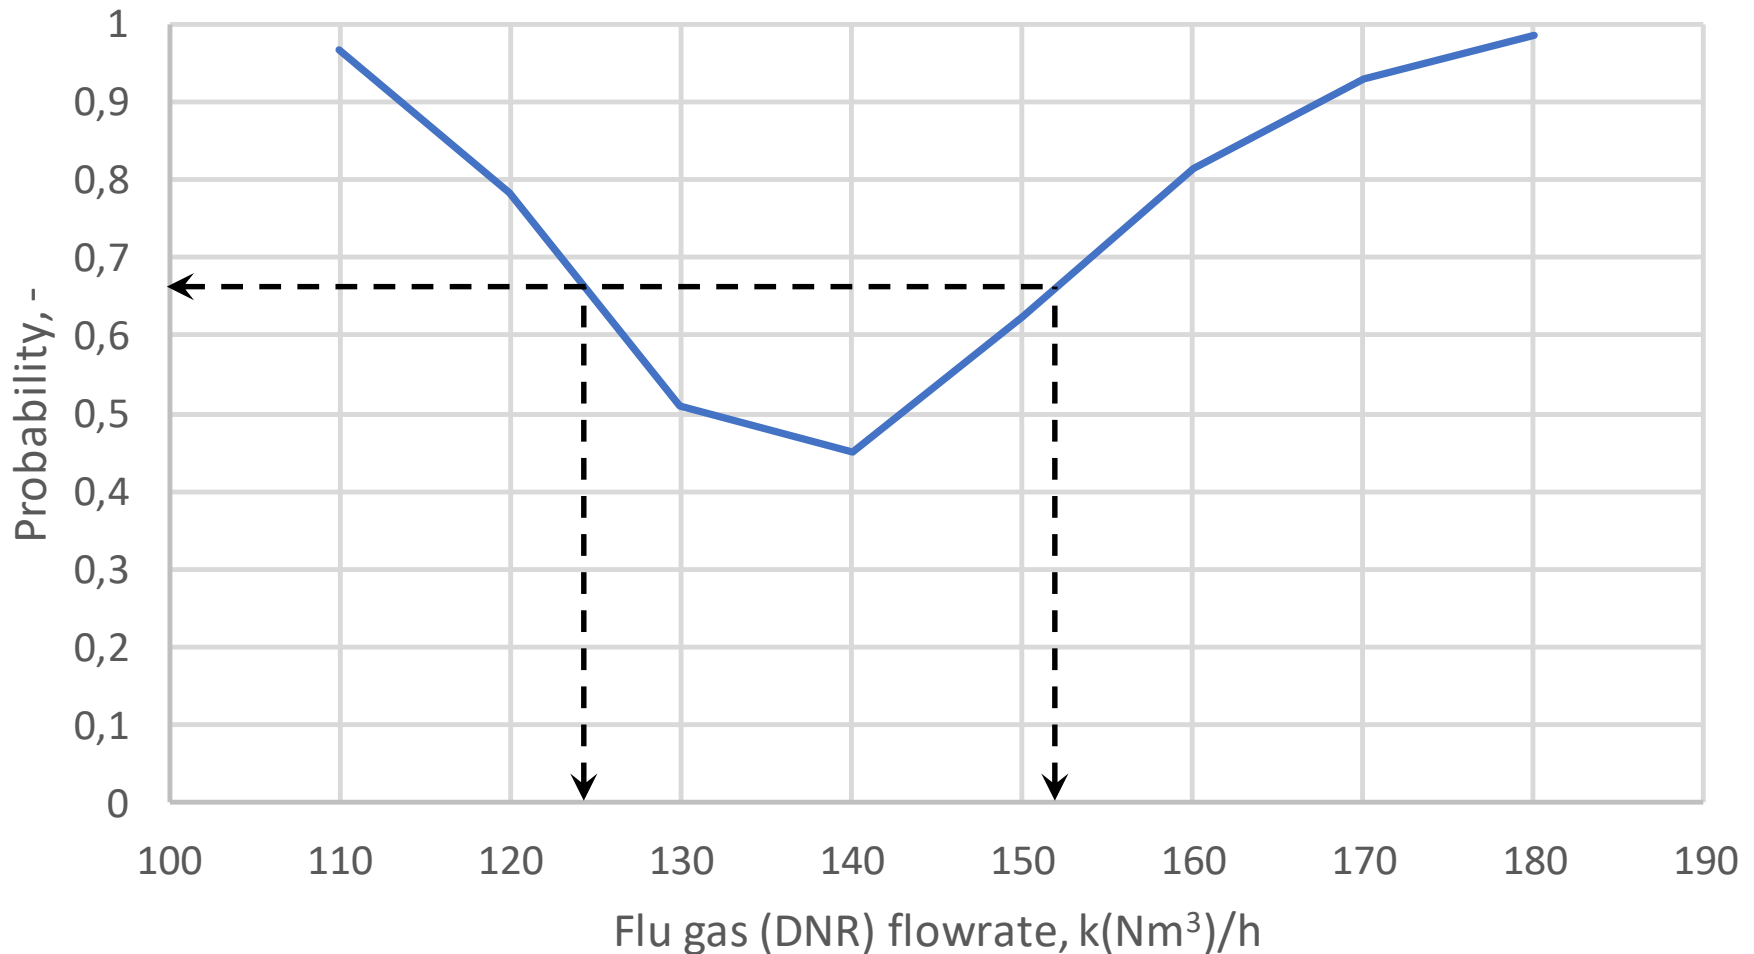

MIN & MAX for waste throughput $\rightarrow M_{W, MIN} < M_W < M_{W, MAX}$

Again MIN & MAX LHV

Find MAX and MIN of FG_{DNR} :

- **6 variables: $M_N, M_H, M_O, M_{N_2}, M_{Ash}, M_{Moist}$ (kg/s);**
- with assigned P_{COMB} (linear function of the 6 variables)
→ **linear equality constraint;**
- under the **6 natural (linear) inequality constraint** (every variable > 0);
- under **12 (linear) inequality constraints** for DAF properties;
- under **6 (linear) inequality constraints** due to technological limitations (y_{Ash}, y_{Moist}, LHV);
- under **2 (linear) inequality constraints** due to operating limitations (M_W);
- under **1 additional (linear) equality constraint** to limit weird solution ($y_{N_2, DAF} = 1\%$ by mass).

**For each level of confidence in the estimate of LHV_{DAF}
→ a linear programming problem in 6 variables with
26 inequality constraints and 2 equality constraints**

FG_{DNR} falls in [124 – 152] k(Nm³)/h @ ~65% conf. → 138 k(Nm³)/h ±10%
FG_{DNR} = 145 k(Nm³)/h ±24.5% @ ~95% confidence level

- **The influence of the nature of the treated waste was investigated with respect to the production of FG_{DNR}**
- **Some constraints on the possible values of waste properties were identified based on a survey of literature data**
- **The behavior of a WtE plant was simulated based on the constraints that represent technological and operating limitations**
- **Although the very conservative approach, the analysis showed that:**
 - **FG_{DNR} basis are known $\pm 10\%$ @ $\sim 65\%$ c.l.**
 - **or $\pm 25\%$ @ $\sim 95\%$ c.l.**
- **This is valid for any type of waste: MSW as well as C&IW**
 - **In fact no evidence of distinctive patterns was found**
- **These results apply to the emissions of those pollutants that depend mainly on FG flowrate**
